

# Deeply Virtual Compton Scattering in Hall C at 11 GeV

Charles Hyde  
Old Dominion  
University

# Why Use Spectrometers for DVCS?

---

- Precision cross sections are key to extracting physics
- $d\sigma(ep \rightarrow ep\gamma) = \text{twist-2 (GPD) terms} + \sum_n [\text{twist-}n]/Q^{n-2}$ 
  - Isolate twist-2 terms  $\rightarrow$  cross sections vs  $Q^2$  at fixed  $(x_{Bj}, t)$ ;
  - Multiple beam energies at fixed  $(Q^2, x_{Bj}, t)$ 
    - Two beam energies at fixed  $(Q^2, x_{Bj}, t)$  to isolate  $[DVCS^{\dagger}BH]$  from  $|DVCS|^2$
    - **Three** beam energies at fixed  $(Q^2, x_{Bj}, t)$  to isolate all twist-2 and twist-3 terms in unpolarized cross section.
- $H(e, e'\gamma)p$  at low  $\Delta^2$ 
  - Electron and photon are highly correlated
  - For a single kinematic setting, Luminosity $\times$ Acceptance (spectrometers) roughly 10 $\times$ CLAS12
    - CLAS12 has greater reach to larger values of  $-t$  and smaller  $x_{Bj}$
    - Spectrometers yield high precision in highest  $Q^2$  bins.

Hall A Helicity Dependent Cross Sections E00-110

PRL97:262002 (2006)  
C. MUNOZ CAMACHO,  
*et al.*,

$\Gamma_{s1,2}$  = kinematic factors

Twist-2(GPD)+...

Twist-3(qGq)+...

$$\sum h d\sigma(h) = \frac{s_1 \sin(\phi_{\gamma\gamma}) \Gamma_{s1} + s_2 \sin(2\phi_{\gamma\gamma}) \Gamma_{s2}}{P_1(\phi_{\gamma\gamma}) P_1(\phi_{\gamma\gamma})}$$

# GPD results from JLab Hall A (E00-110) (C.MUNOZ CAMACHO et al PRL 97:262002)

- $Q^2$ -independance of  $\text{Im}[DVCS^*BH]$ 
  - Twist-2 Dominance (GPD)
  - Model « Vanderhaeghen-Guichon-Guidal(VGG) »  
(based on Double Dist. of A.Radyushkin) accurate to  $\approx 30\%$

Extend to  
 $Q^2 = 4.5 \text{ GeV}^2$   
@11GeV

Compensate the small lever-arm in  $Q^2$  with precision in  $d\sigma$ .

## Beam helicity-independent cross sections at $Q^2=2.3 \text{ GeV}^2$ , $x_B=0.36$

- Contribution of  $\text{Re}[DVCS^*BH] + |DVCS|^2$  large.
- Positron beam or measurements at multiple incident energies to separate these two terms and isolate Twist 2 from Twist-3 contributions

PRL97:262002 (2006) C.  
MUNOZ CAMACHO, *et al.*

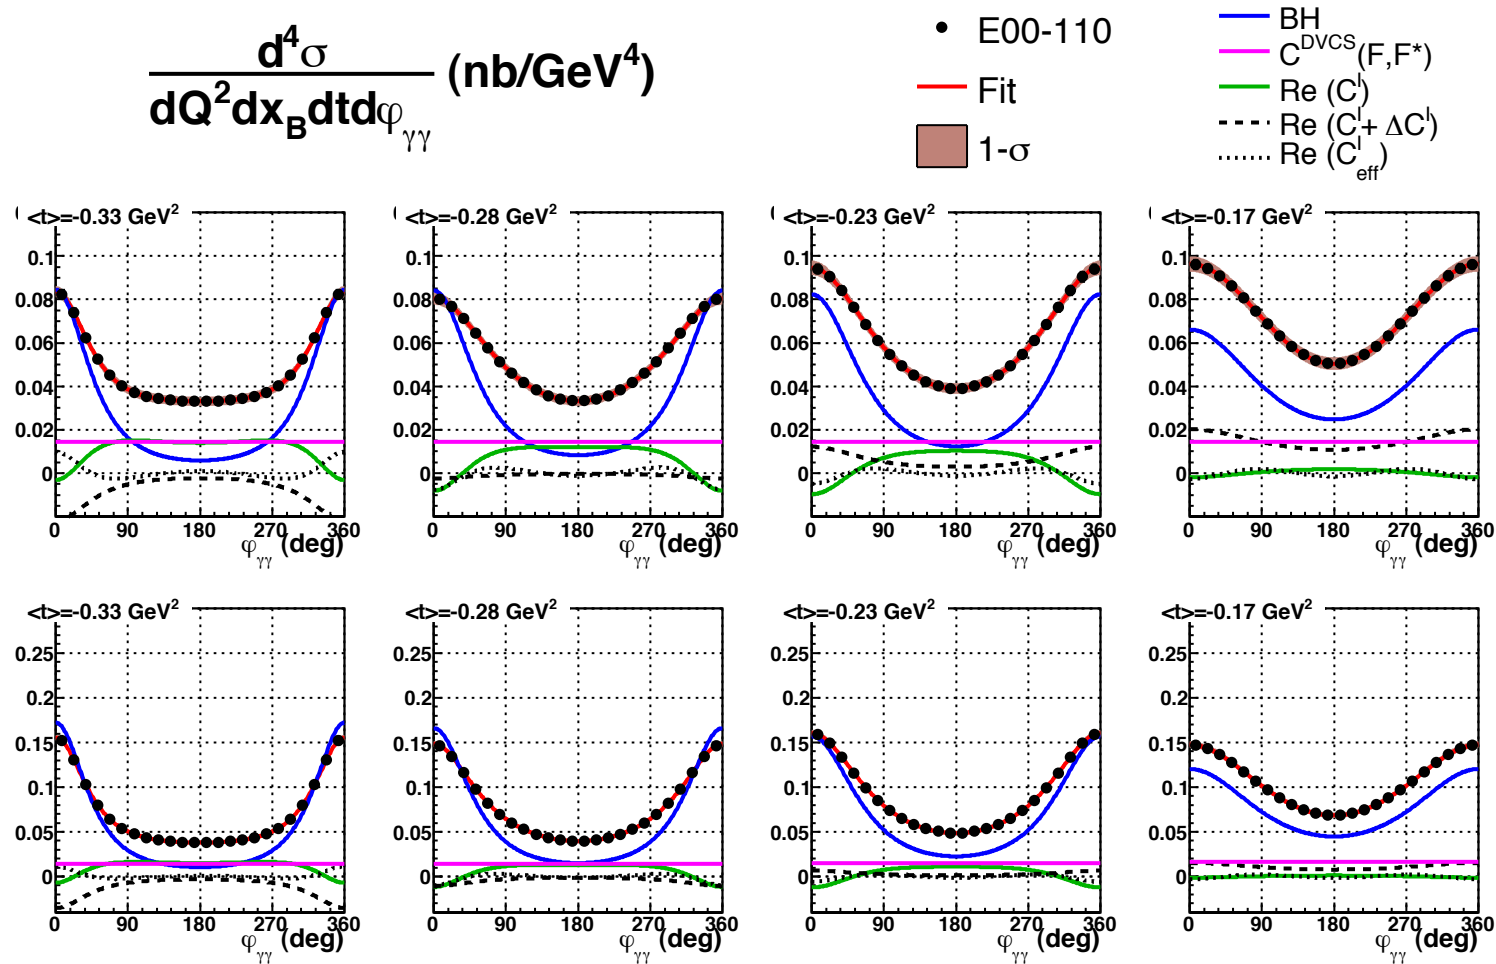

$$\begin{aligned}
 d\sigma &= d\sigma(|BH|^2) + 2\text{Re}[DVCS^*BH] + |DVCS|^2 \\
 &= d\sigma(|BH|^2) + \frac{c_0\Gamma_0 + c_1 \cos(\phi_{\gamma\gamma})\Gamma_1 + c_2 \cos(2\phi_{\gamma\gamma})\Gamma_2 + \dots}{P_1(\phi_{\gamma\gamma})P_1(\phi_{\gamma\gamma})}
 \end{aligned}$$

$$\begin{aligned}
 c_{0,1}(t) &\approx \text{Re}[C^I(GPD)] \pm C^{DVCS}(GPD^2) \dots + \text{Re}[\Delta C^I(GPD)] \\
 c_2(t) &= \text{Twist} - 3 = (qGq)
 \end{aligned}$$

# Projections for E07-007 (2010), $Q^2=1.9 \text{ GeV}^2$

- Different dependence on incident energy for  $|BH|^2$ ,  $[DVCS^\dagger BH]$  ( $C^I$  twist-2), and  $|DVCS|^2$  ( $C^{DVCS}$  twist-3) terms

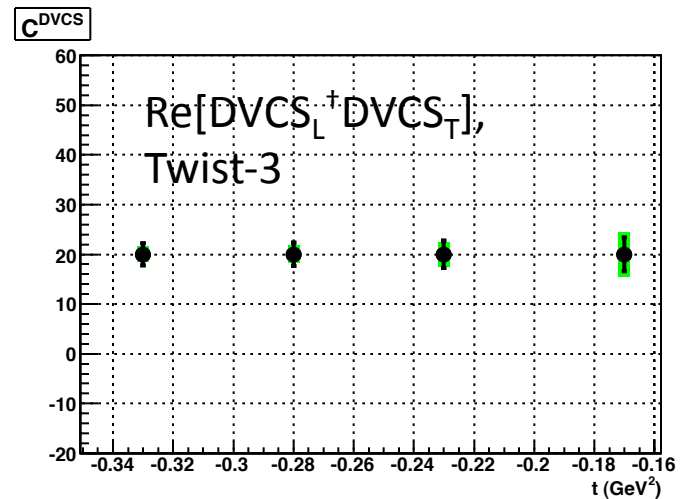

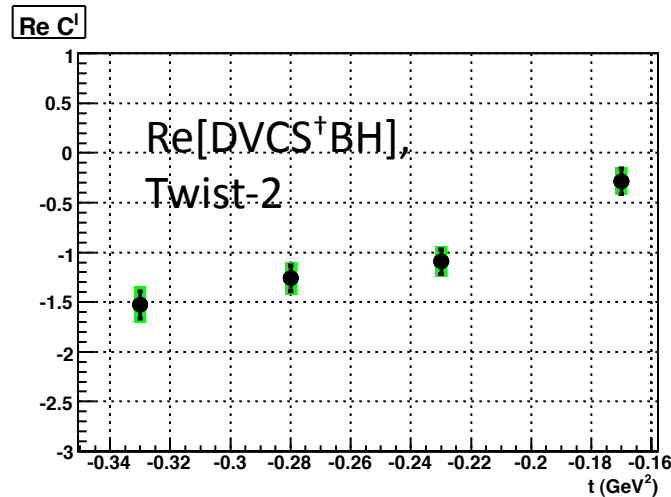

$k = 6 \text{ GeV}$

$k = 4.8 \text{ GeV}$

# E07-007 Projected Extractions:

- green bands are systematic errors.
- Four different contributions to unpolarized cross sections
  - constant terms
  - $\cos\phi_{\gamma\gamma}$  terms
  - $\cos 2\phi_{\gamma\gamma}$  terms

# Hall A E12-06-116, approved for 100 days

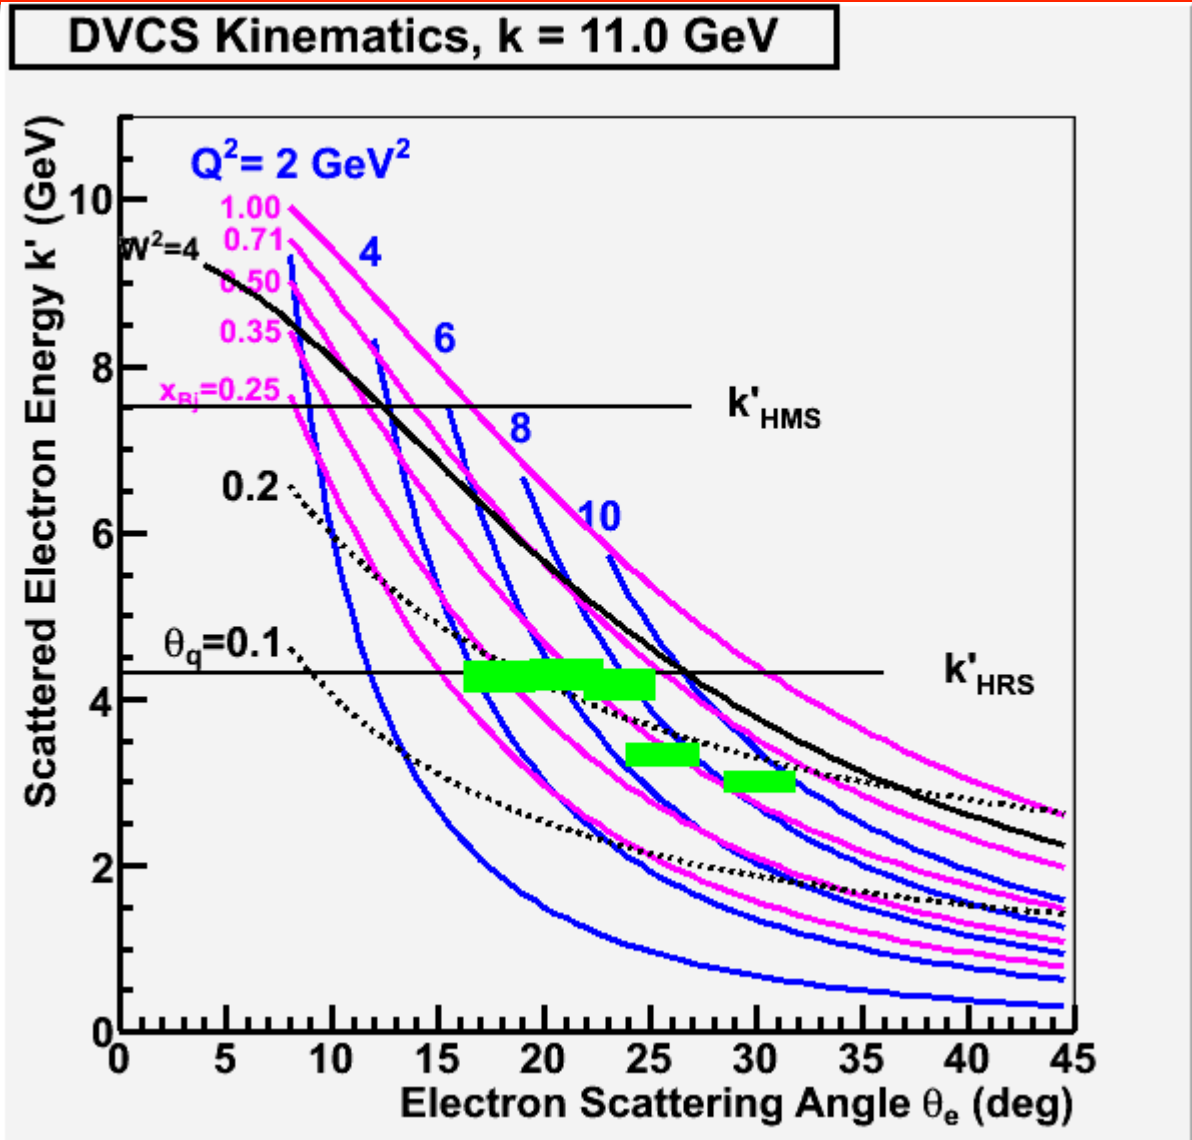

- Multiple beam energies at fixed  $Q^2$ ,  $x_{Bj}$  requires spectrometer momenta  $> k_{HRS}=4.3$  GeV/c

# DVCS Kinematics, Hall A & C

- Green rectangles are Hall A kinematics.
- Calorimeter centered at  $\theta_q$ .
  - Require  $\theta_q \geq 0.2$  rad to avoid small-angle background.

# Calorimeter Issues

---

- Distance from target is dictated by  $\pi^0 \rightarrow \gamma\gamma$  opening angle and Calorimeter Moliere radius (transverse shower profile).
  - Optimum to be able to vary Target to Calo distance in range 2-4 m for DVCS data, and to  $\geq 5$  m for calibration
- Angular size is dictated by:
  - $t_{\text{Min}} - t$  acceptance desired
  - $t_{\text{Min}} - t$  acceptance must be convoluted with  $\pi^0 \rightarrow \gamma\gamma$
- High backgrounds require
  - Fast response
  - Radiation hard
  - Sweep magnet to get to central Calorimeter angles  $< 10^\circ$

---

Longitudinal and Transverse Polarized Targets  
for DVCS at 11 GeV:

Required for separation of  
 $H, E, \tilde{H}, \tilde{E}$  GPDs  
*on  $x=\xi$  line.*

## Polarized Protons, Neutrons in CLAS12

---

- Longitudinally polarized  $\text{NH}_3$  target
  - 100 days approved
  - polarized proton luminosity  $\sim 10^{34}$  ?
  - Extensive data taken already at 6 GeV
- Transversely polarized protons in HDice
  - C2 approval from PAC, pending luminosity and polarization milestones
- Longitudinal  $\text{ND}_3$  or LiD likely (proposals?)
  - Unpolarized  $\text{D}_2$  program with Orsay neutron detector in central barrel
- No active program for transversely polarized neutrons

# High Luminosity Polarized $^3\text{He}$ Target

## The requirements:

60% with  $60\ \mu\text{A}$  on a 60 cm target at 11-12 atm

30 cm

Neutron  
 $\mathcal{L} = 3 \cdot 10^{36}$

- Convection-based cell to avoid polarization gradients at high current.
- Expanded vertical dimension will allow radiation shielding.
- Larger volume of polarized gas will enable target to tolerate higher beam depolarization.
- Metal target cell to better tolerate high beam (or at least metal endcaps).

Need thin metal walls, or 6 cm  $\phi$  cell, to eliminate secondary background in DVCS Calorimeter

# Neutron DVCS in $^3\text{He}$ Target:

$$\vec{n}(\vec{e}, e' \gamma) n \text{ via } {}^3\vec{H}e(\vec{e}, e\gamma) X$$

- Target spin-dependent cross sections
  - $0.86''n''-0.028''p''$  from  ${}^3\text{He}$  wave-function
- Fermi-motion of neutron in  ${}^3\text{He}$ 
  - Smearing of QF neutron contribution with pion-production channels  $N(e, e' \gamma) N\pi$
  - $H(e, e' \gamma) X$ :  $M_X^2$  resolution  $\sigma(M_X^2) \approx 0.22 \text{ GeV}^2$ .
  - For  $-t < 0.4 \text{ GeV}^2$  and  $p_N < 250 \text{ MeV}/c$ , QF smearing contributes  $\leq 0.1 \text{ GeV}^2$  to  $\sigma(M_X^2)$ .

Benhar, Day, Sick,  
RMP80 (2008)

FIG. 19. Scaling function for  ${}^3\text{He}(e, e')$ . The various data sets are labeled by electron energy (MeV) and angle (deg).

# Neutron DVCS Observables

---

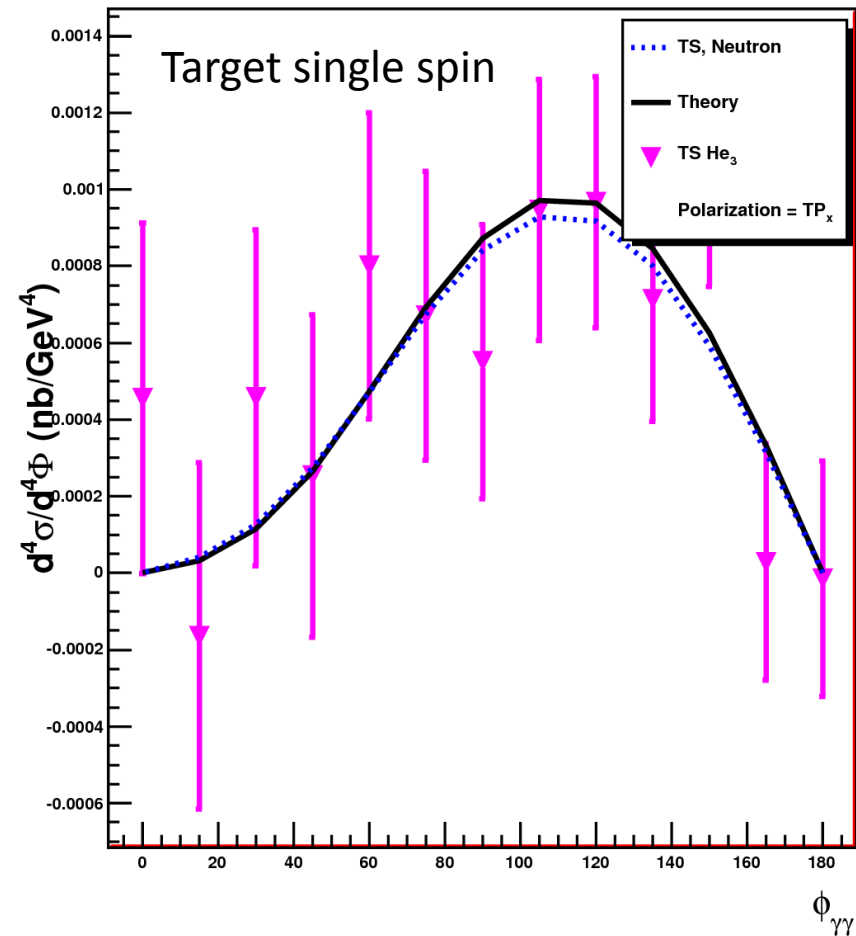

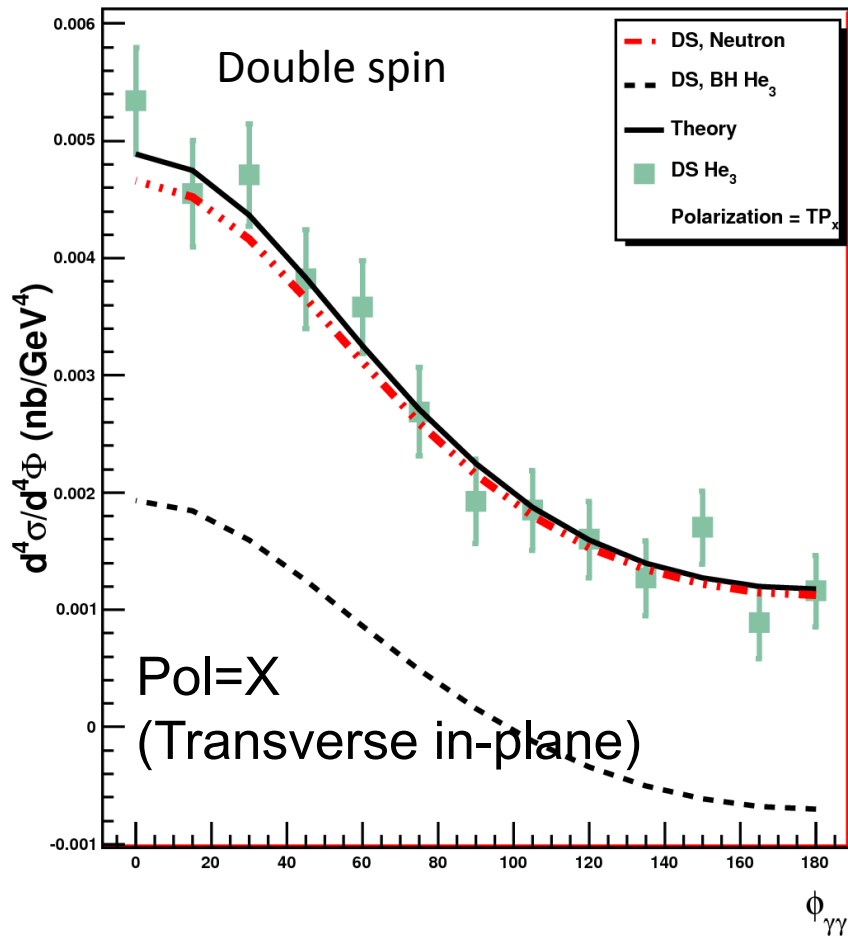

$d\sigma(\lambda, \Lambda)$  for  $\vec{n}(\vec{e}, e' \gamma)n$  via  ${}^3\vec{H}e(\vec{e}, e\gamma)X$

$\lambda, \Lambda$  = electron,  ${}^3\text{He}$  Polarization

- Long or Transverse Normal Polarization
- Target Single Spin Cross Sections
  - $d\sigma_{\text{LSS}} = \sum_{\lambda\Lambda} \Lambda d\sigma(\lambda, \Lambda)/4 \sim \sin\phi_{\gamma\gamma}$   
Im[BH\*DVCS] (Twist-2)  
Unpolarized Protons in  ${}^3\text{He}$  cancel
- Target Double Spin
  - $d\sigma_{\text{LDS}} = \sum_{\lambda\Lambda} \Lambda \lambda d\sigma(\lambda, \Lambda)/4 \sim c_0 + c_1 \cos\phi_{\gamma\gamma}$   
Re[BH<sup>2</sup> + (BH\*DVCS) + DVCS<sup>2</sup>]  
Unpolarized protons cancel
- Transverse Sideways:  $\sin\phi_{\gamma\gamma} \Leftrightarrow \cos\phi_{\gamma\gamma}$
- All other “neutron” observables ( $d\sigma$ , Beam-spin) have large incoherent proton contributions

$$Q^2 = 3.05 \text{ GeV}^2, x_{Bj}=0.36, t_{Min}-t=0.05 \text{ GeV}^2$$

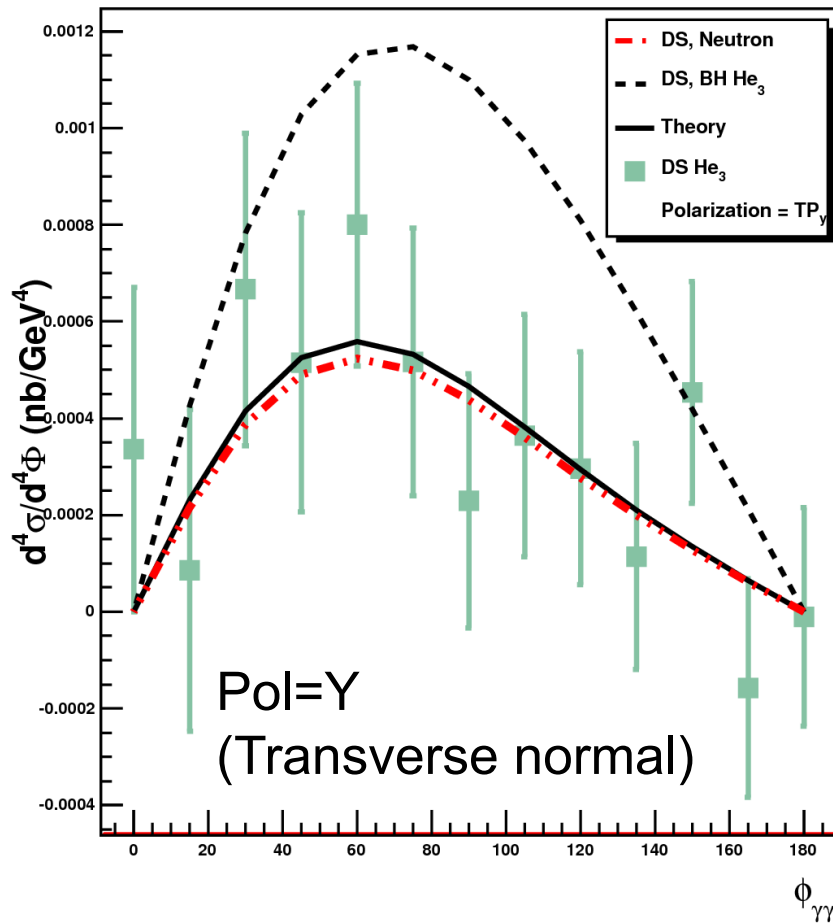

$$\Delta t=0.10 \text{ GeV}^2, 16 \text{ days @ } 3 \cdot 10^{36} \times 60\% \times 80\%$$

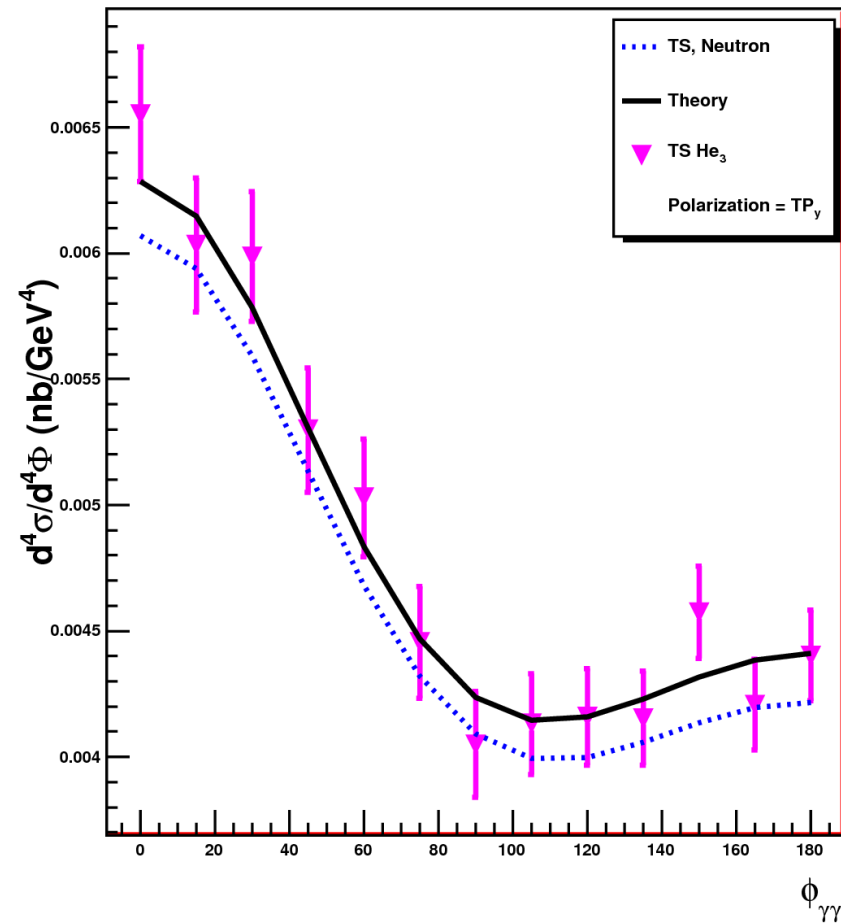

$$Q^2 = 3.05 \text{ GeV}^2, x_{Bj}=0.36, t_{Min}-t=0.05 \text{ GeV}^2$$

$$\Delta t=0.10 \text{ GeV}^2, 16 \text{ days @ } 3 \cdot 10^{36} \times 60\% \times 80\%$$

Double spin

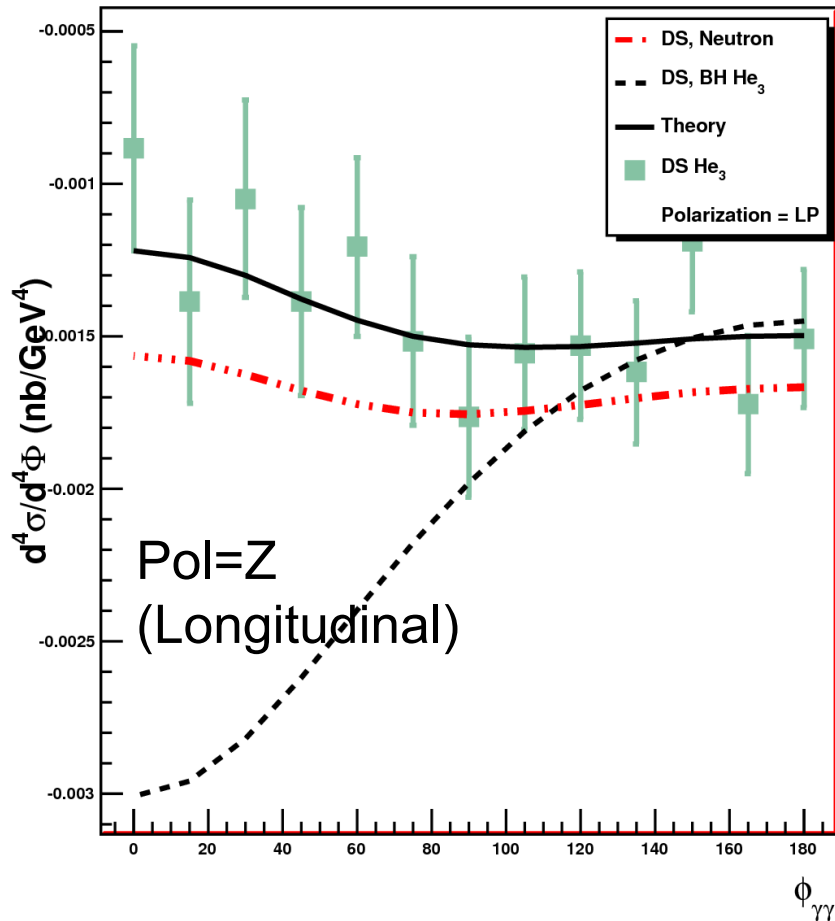

Target single spin

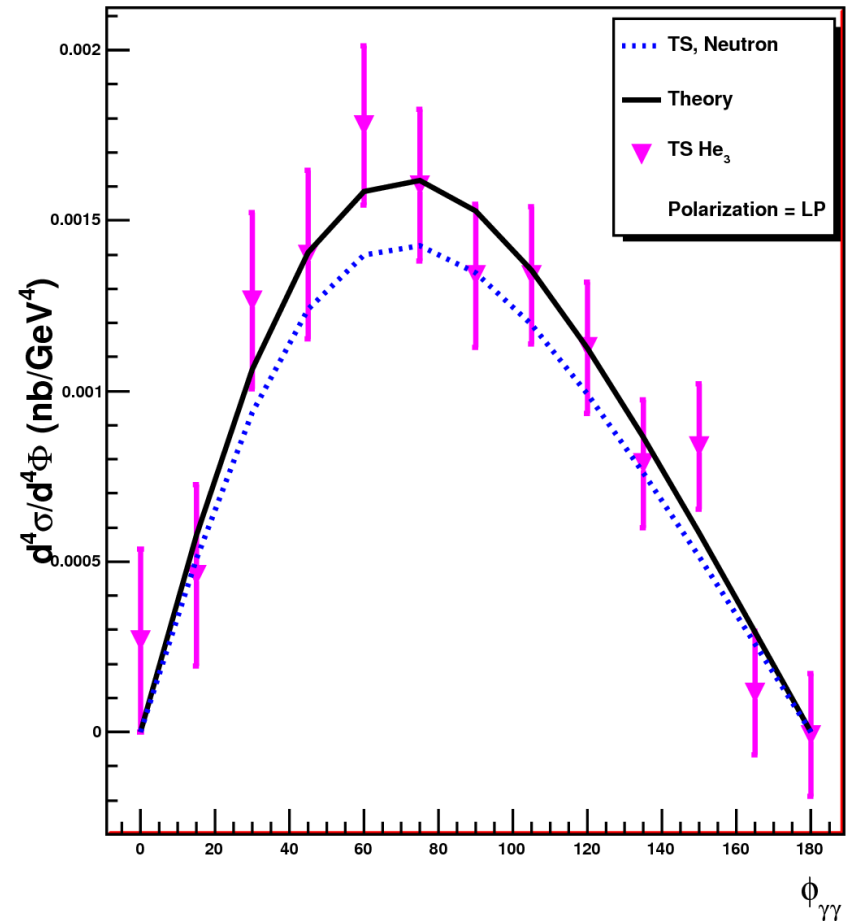

$$Q^2 = 3.05 \text{ GeV}^2, x_{Bj} = 0.36, t_{Min} - t = 0.05 \text{ GeV}^2$$

$$\Delta t = 0.10 \text{ GeV}^2, 16 \text{ days @ } 3 \cdot 10^{36} \times 60\% \times 80\%$$

Double spin

Target single spin

# Conclusions

---

- Precision cross section measurements with spectrometers are essential to extracting leading twist amplitudes from the  $ep \rightarrow ep\gamma$  cross section
- The Hall C HMS paired with the DVCS  $\text{PbF}_2$  calorimeter (or alternate  $\text{PbWO}_4$ ) will allow an extension to measure additional energy points for each  $x_{Bj}$  value (at one or two  $Q^2$  values)
  - Separation of all twist-2 and twist-3 contributions to unpolarized cross sections, without positrons.
- A new sweep magnet, and a rad-hard calo will allow extensions to lower  $x_{Bj}$  and higher  $Q^2$  (closer to kinematic limits)
- Polarized  $^3\text{He}$  targets are only present option for transversely polarized 'neutron' target.
  - Measurement of  $E_n(\xi, \xi, t)$  at 10—15% precision for 16 days per  $(Q^2, \xi)$  point.

# Deep Virtual $\eta$ -Production

---

- $H(e, e' \eta) p$ 
  - *Detect via  $\eta \rightarrow \gamma\gamma$*
  - *Strangeness?*
  - *Axial anomaly?*
- Requires a much larger calorimeter
  - $\gamma\gamma$  cone half-angle  $\approx 4\times$  larger for  $\eta$  than  $\pi^0$
  - Roughly  $\pm 100$  mrad at  $Q^2=4.0 \text{ GeV}^2$ ,  $x_{Bj} = 0.36$

$$Q^2 = 3.05 \text{ GeV}^2, x_{Bj}=0.36, t_{Min}-t=0.05 \text{ GeV}^2$$

$$\Delta t=0.10 \text{ GeV}^2, 16 \text{ days @ } 3 \cdot 10^{36} \times 60\% \times 80\%$$

One- $\sigma$  sensitivity  $\Delta(J_{ll}, J_d) = 0.06$  (parameters of  $E$  in VGG model)

# Missing Mass Resolution

- Spectrometer resolution required

- $\delta p/p \leq 10^{-3}$
- $\delta\theta \sim 10^{-3}$

# Electron and Gamma-ray Backgrounds dominate

- Target dominates background
- Sweeping magnet  $\rightarrow$  Background/10

# DVCS Kinematics, Hall A & C

- Green rectangles are Hall A kinematics.
- Calorimeter centered at  $\theta_q$ .
  - Require  $\theta_q \geq 0.2$  rad to avoid small-angle background
