

Voltage Controlled Oscillator

Consider MC12148 for New Designs

The MC1648 requires an external parallel tank circuit consisting of the inductor (L) and capacitor (C). **For Maximum Performance $Q_L \geq 100$ at Frequency of Operation.**

A varactor diode may be incorporated into the tank circuit to provide a voltage variable input for the oscillator (VCO). The MC1648 was designed for use in the Motorola Phase-Locked Loop shown in Figure 9. This device may also be used in many other applications requiring a fixed or variable frequency clock source of high spectral purity. (See Figure 2)

The MC1648 may be operated from a +5.0Vdc supply or a -5.2Vdc supply, depending upon system requirements.

NOTE: The MC1648 is NOT useable as a crystal oscillator.

MC1648 NON-STANDARD PIN CONVERSION DATA

Package	TANK	VCC	VCC	OUT	AGC	VEE	VEE	BIAS
8 D	1	2	3	4	5	6	7	8
14 L,P	12	14	1	3	5	7	8	10
20FN	18	20	2	4	8	10	12	14

*NOTE – All unused pins are not connected.

Supply Voltage	GND Pins	Supply Pins
+5.0Vdc	7,8	1,14
-5.2Vdc	1,14	7,8

LOGIC DIAGRAM

- Input Capacitance = 6.0pF (TYP)
- Maximum Series Resistance for L (External Inductance) = 50Ω (TYP)
- Power Dissipation = 150mW (TYP)/Pkg (+5.0Vdc Supply)
- Maximum Output Frequency = 225MHz (TYP)

VCC1 = Pin 1
VCC2 = Pin 14
VEE = Pin 7

2. Frequency variation over temperature is a direct function of the ΔC/Δ Temperature and ΔL/Δ Temperature.

Figure 3. Test Circuit and Waveforms

OPERATING CHARACTERISTICS

Figure 1 illustrates the circuit schematic for the MC1648. The oscillator incorporates positive feedback by coupling the base of transistor Q6 to the collector of Q7. An automatic gain control (AGC) is incorporated to limit the current through the emitter-coupled pair of transistors (Q7 and Q6) and allow optimum frequency response of the oscillator.

In order to maintain the high Q of the oscillator, and provide high spectral purity at the output, transistor Q4 is used to translate the oscillator signal to the output differential pair Q2 and Q3. Q2 and Q3, in conjunction with output transistor Q1, provides a highly buffered output which produces a square wave. Transistors Q9 and Q11 provide the bias drive for the oscillator and output buffer. Figure 2 indicates the high spectral purity of the oscillator output (pin 3).

When operating the oscillator in the voltage controlled mode (Figure 4), it should be noted that the cathode of the varactor diode (D) should be biased at least "2" V_{BE} above

- * Use high impedance probe (>1.0 Megohm must be used).
- ** The 1200 ohm resistor and the scope termination impedance constitute a 25:1 attenuator probe. Coax shall be CT-070-50 or equivalent.
- *** Bypass only that supply opposite ground.

V_{EE} (≈1.4V for positive supply operation).

When the MC1648 is used with a constant dc voltage to the varactor diode, the output frequency will vary slightly because of internal noise. This variation is plotted versus operating frequency in Figure 5.

Figure 4. The MC1648 Operating in the Voltage Controlled Mode

Oscillator Tank Components (Circuit of Figure 4)

f MHz	D	L μH

** Input resistor and cap are for test only. They are NOT necessary for normal operation.

Typical transfer characteristics for the oscillator in the voltage controlled mode are shown in Figure 6, Figure 7 and Figure 8. Figure 6 and Figure 8 show transfer characteristics employing only the capacitance of the varactor diode (plus the input capacitance of the oscillator, 6.0pF typical). Figure 7 illustrates the oscillator operating in a voltage controlled mode with the output frequency range limited. This is achieved by adding a capacitor in parallel with the tank circuit as shown. The 1.0k Ω resistor in Figure 6 and Figure 7 is used to protect the varactor diode during testing. It is not necessary as long as the dc input voltage does not cause the diode to become forward biased. The larger-valued resistor (51k Ω) in Figure 8 is required to provide isolation for the high-impedance junctions of the two varactor diodes.

The tuning range of the oscillator in the voltage controlled mode may be calculated as:

$$\frac{f_{\max}}{f_{\min}} = \frac{\sqrt{C_D(\max) + C_S}}{\sqrt{C_D(\min) + C_S}}$$

$$\text{where } f_{\min} = \frac{1}{2\pi \sqrt{L(C_D(\max) + C_S)}}$$

CS = shunt capacitance (input plus external capacitance)

CD = varactor capacitance as a function of bias voltage

Good RF and low-frequency bypassing is necessary on the power supply pins. (See Figure 2)

Capacitors (C1 and C2 of Figure 4) should be used to bypass the AGC point and the VCO input (varactor diode), guaranteeing only dc levels at these points.

For output frequency operation between 1.0MHz and 50MHz a 0.1 μ F capacitor is sufficient for C1 and C2. At higher frequencies, smaller values of capacitance should be used; at lower frequencies, larger values of capacitance. At high frequencies the value of bypass capacitors depends directly upon the physical layout of the system. All bypassing should be as close to the package pins as possible to minimize unwanted lead inductance.

The peak-to-peak swing of the tank circuit is set internally by the AGC circuitry. Since voltage swing of the tank circuit provides the drive for the output buffer, the AGC potential directly affects the output waveform. If it is desired to have a sine wave at the output of the MC1648, a series resistor is tied from the AGC point to the most negative power potential (ground if +5.0 volt supply is used, -5.2 volts if a negative supply is used) as shown in Figure 10.

At frequencies above 100 MHz typ, it may be desirable to increase the tank circuit peak-to-peak voltage in order to shape the signal at the output of the MC1648. This is accomplished by tying a series resistor (1.0k Ω minimum) from the AGC to the most positive power potential (+5.0 volts if a +5.0 volt supply is used, ground if a -5.2 volt supply is used). Figure 11 illustrates this principle.

APPLICATIONS INFORMATION

The phase locked loop shown in Figure 9 illustrates the use of the MC1648 as a voltage controlled oscillator. The figure illustrates a frequency synthesizer useful in tuners for FM broadcast, general aviation, maritime and landmobile communications, amateur and CB receivers. The system operates from a single +5.0Vdc supply, and requires no internal translations, since all components are compatible.

Frequency generation of this type offers the advantages of single crystal operation, simple channel selection, and elimination of special circuitry to prevent harmonic lockup. Additional features include dc digital switching (preferable over RF switching with a multiple crystal system), and a broad range of tuning (up to 150MHz, the range being set by the varactor diode).

The output frequency of the synthesizer loop is determined by the reference frequency and the number programmed at the programmable counter; $f_{\text{out}} = Nf_{\text{ref}}$. The channel spacing is equal to frequency (f_{ref}).

For additional information on applications and designs for phase locked-loops and digital frequency synthesizers, see

Motorola Brochure BR504/D, Electronic Tuning Address Systems, (ETAS).

Figure 10 shows the MC1648 in the variable frequency mode operating from a +5.0Vdc supply. To obtain a sine wave at the output, a resistor is added from the AGC circuit (pin 5) to VEE.

Figure 11 shows the MC1648 in the variable frequency mode operating from a +5.0Vdc supply. To extend the useful range of the device (maintain a square wave output above 175MHz), a resistor is added to the AGC circuit at pin 5 (1.0 kohm minimum).

Figure 12 shows the MC1648 operating from +5.0Vdc and +9.0Vdc power supplies. This permits a higher voltage swing and higher output power than is possible from the MECL output (pin 3). Plots of output power versus total collector load resistance at pin 1 are given in Figure 13 and Figure 14 for 100MHz and 10MHz operation. The total collector load includes R in parallel with R_p of L1 and C1 at resonance. The optimum value for R at 100MHz is approximately 850 ohms.
