- 1 Problem with  $E$  in Farm-Replayed  $^2\text{H}$  Runs
- 2 Vertex-Z Cut
- 3 More on Čerenkov Cuts
  - Čerenkov ADC Cut
  - Čerenkov TDC Timing
- 4 Summary
- 5 What's Next?

## Problem with $E$ in Farm-Replayed $^2\text{H}$ Runs

- Matt noticed a problem with reconstructed  $E$  in runs 1258-1262 (hydrogen one-pass coincidence runs)
- $E/p$  was peaking around 1.7 instead of 1.0 – but it was correct earlier in the day ( $^3\text{He}$  target)
- Turns out that StartType.pl was sourcing an outdated DB file for some subsets of runs
- None of our four-pass production dataset was affected

# Vertex-Z Cut

- It looks like the vertex-z distribution changed dramatically during production running
- Does anyone know why?

## Run 1449 (5.9 GeV, Feb 15)

## Runs 1972-1981 (5.9 GeV, Mar 4)

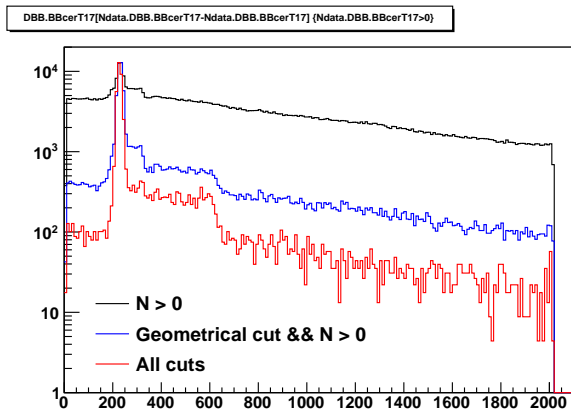

# Čerenkov ADC Cut

- Matt showed that, by itself, a 3-p.e. ADC cut did a good job cutting out pions from a T6 sample
- In conjunction with the rest of our cut set, is this cut justified?
- Dropping the ADC cut increases our statistics by 14.1%

# Čerenkov TDC Timing

- To better understand the TDC timing spectrum, let's look at how well our other cuts remove accidentals ...

# Summary

- $E$  problem in one-pass runs is easily fixed
- Vertex  $z$  position distribution changed during experiment
- Čerenkov ADC software cut does not clean up our sample's  $E/p$  behavior
- TDC spectrum: non-accidentals are confined to the sharp peak, but the shoulder shape is mysterious

# What's Next?

- Cuts
  - ▶ Čerenkov cut consistency
  - ▶ Confirm times of HWP switches
- Asymmetries
  - ▶ Elastic  $^3\text{He}$  asymmetry to check sign
  - ▶ Asymmetry on particles that scattered from pole piece
  - ▶ Asymmetry on new good electron sample
  - ▶ Nitrogen dilution factor
- Compton
  - ▶ Replay of Saclay-daq Compton files
  - ▶  $P_\gamma$
  - ▶ Produce single  $P_e$  for each run period
- Dissertation
